Module 2: Genome Browsing

Aims

- Explain why it can be useful to look at the whole genome.
- Discuss how genes and other features can be predicted and displayed.
- Briefly present the main web-based genome browsers.
- Using Ensembl, demonstrate some of the features and applications of genome browsers.
- Introduce the BioMart data retrieval system.
- Examples (include location and structure of a known gene and its products; information about a defined chromosomal region; convenient export of selected information).

Introduction

Web-based 'genome browsers' have been developed to make it easier to access comprehensive information about regions of the human genome and about the whole human gene set. They help you to:

- Explore what is in a chromosomal region
- See features in and around a specific gene
- Search & retrieve across the whole genome
- Investigate genome organisation
- Compare to other genomes

Browsers display the location and structure of known genes and predicted novel genes along with information about the mRNA transcripts and may also include information about protein products. Information about genes is integrated with information about other genomic features (e.g. cytogenetic bands, markers, SNPs, repeated sequences, regions homologous to other species) and displayed alongside the genomic sequence assembly. Protein, mRNA and EST entries from various sequence databases may also be shown 'mapped' onto the chromosomes.

In addition to providing annotation across the whole genome, browsers provide other resources. The browsers differ in what is provided and how it is presented. Resources that can be found include:

- Links to other databases and resources
- Text Searching
- BLAST and other sequence similarity searching
- Download of genomic sequence, gene information and other data
- Data mining facilities

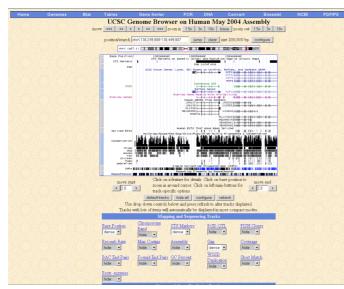

Browsers (and some of their strengths)

- NCBI Map Viewer maintained by NCBI <u>http://www.ncbi.nlm.nih.gov/mapview/</u>
- UCSC Genome Browser maintained by UCSC
 <u>http://genome.ucsc.edu/cgi-bin/hgGateway</u>
- Ensembl maintained by EBI / Sanger Institute
 <u>http://www.ensembl.org</u>

NCBI Map Viewer

Good integration with other NCBI resources

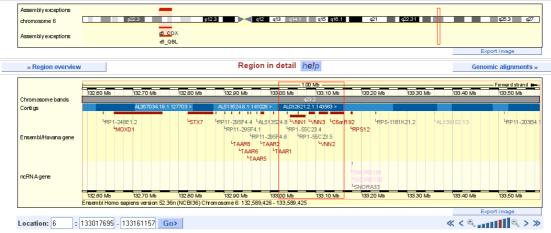

UCSC Genome Browser

Straightforward feature display Old assemblies available Wide range of tracks supplied by other groups

Ensembl

Well-supported gene set with evidence Range of different views Easy retrieval of data sets Archive available

Chromosome 6: 133,017,695-133,161,157

While browsers can be very useful tools, they do not provide the definitive answer to every question! Remember, new data and updates make genome browsing a fluid, changing, and improving, process.

Data retrieval and data mining

Genomic annotation data, due to its complexity and volume, does not lend itself to easy access. Presenting it on a web site is important, but so is providing simple but flexible ways to select and retrieve specific sets of data. NCBI has the Entrez query system and UCSC has its Table Browser.

In Ensembl, BioMart facilitates rapid retrieval of richly annotated gene lists, sequences, and SNP details, among other annotation, integrated with third party data and applications. Genes can be selected by chromosome region, protein domains, associated external identifiers or SNP properties, and these filters can be combined to group and refine biological data, including cross-species analyses, disease links, sequence variations and expression patterns.

BioMart is built upon a query-optimised relational database schema allowing quick and efficient access to voluminous data through a user-friendly, interactive web interface. After selecting the biological object and the species, the results can be refined using a set of pre-defined filters. After each navigation event, the user is provided with immediate feedback on the number of matches found. Output can consist of annotated gene lists, gene structures, SNP details or various kinds of sequence sets. Output can be in HTML, text, Microsoft Excel and compressed formats.

WALKING THROUGH THE WEBSITE

The instructor will guide you through the website using the **Nuclear respiratory factor 1 (nrf1)** gene. The following points will be addressed:

• The Gene Summary tab and gene-related links:

- Are there splice variants?
- Can I view the genomic sequence with variations?
- Find orthologues and paralogues
- The Transcript tab and related links:
 - What is the protein sequence?
 - What matching proteins and mRNAs are found in other databases?
 - Gene Ontology

• The Location tab and related links:

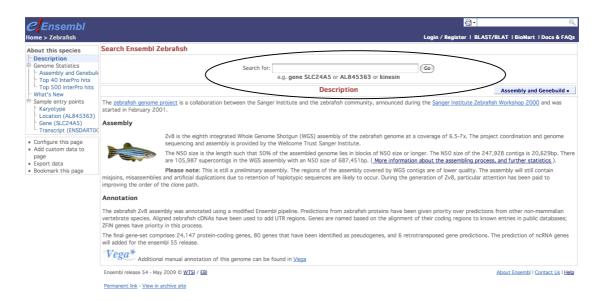

- What's the conservation track?
- How do I zoom in and change the gene focus.
- Un-stacking a track (e.g. human cDNAs)
- Adding a track (i.e. variations)

• Exporting a sequence and running BLAT/BLAST

Start by going to **www.ensembl.org**

Click on 'Zebrafish', or the picture circled above, which brings us to the species index page.

Type 'gene nrf1' into the search bar circled above and click the 'Go' button.

Look through the search results for the appropriate candidates (i.e. *nrf1* is assigned as the gene symbol). In this worked example there is only one search result, but there can be plenty. The following 'Gene' tab will open:

Have you forgotten what the colours mean? No worries- click on the 'Help' button (circled in red) and read the help for this page. A link to the **glossary** is also provided.

Next, follow the **'Supporting Evidence'** link. The following data display is quite an important one, as it shows which biological evidence has been used for the annotation of this transcript. Red boxes:

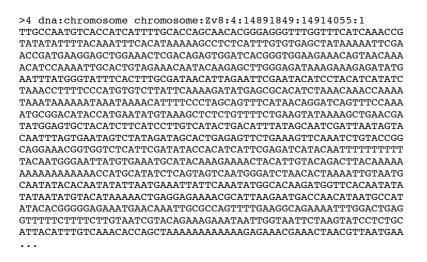

Other transcript-specific displays include the cDNA sequence, general identifiers and gene ontology terms from the GO consortium (www.geneontology.org).

Let's now view the genomic region in which this gene and its transcript have been annotated by clicking onto the **'Location'** tab.

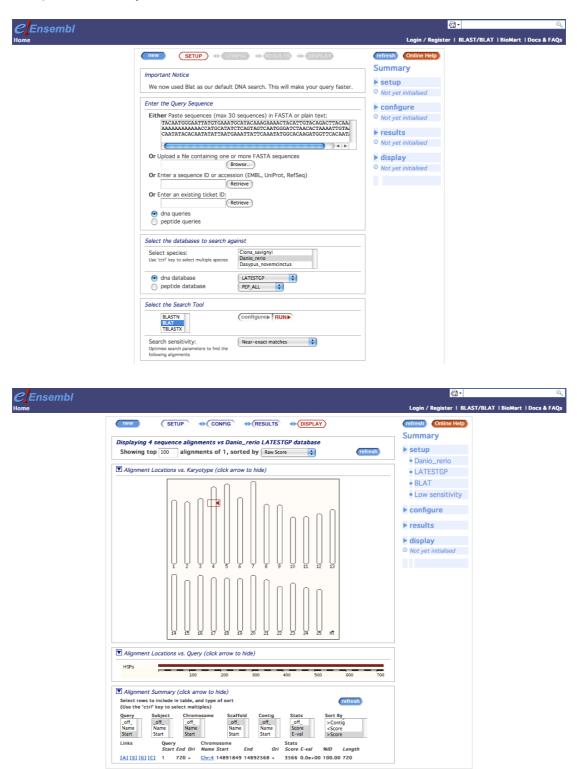

Ensembl 'Location' displays are also highly configurable. You can switch on additional tracks displaying the various feature types that Ensembl annotates in the genome. Again, to enter the configuration dialogue, use the 'Configure this page' link. As an exercise, add 'all variations' to the 'Region in detail' display and view the 'cDNAs' track in 'normal' expanded form.

After investigating the 'Location' display, we would like to export genomic sequence. Click the 'Export location data' option and select the 'FASTA' sequence format.

Select the header and a few lines of sequence and then follow the 'BLAST/BLAT' link in the blue header bar. Paste the sequence into the

appropriate box and select 'BLAT' as the search algorithm and 'Danio_rerio' as species. Finally, click 'Run'.

Finally, follow links to an alignment **[A]**, the query sequence **[S]**, the genome sequence **[G]** and the corresponding Location-View **[C]** (for its former name ContigView... or to C (see) the BLAST hit!

EXERCISES and ANSWERS

Note: The answers to these exercises correspond to version 54 of Ensembl. If you use a newer version and your answer doesn't correspond with the given answer, please consult the instructors. Alternatively, you can use version 54 from the Ensembl Archive site.

Exercise 1 – Exploring a gene

(a) Search for the zebrafish pax6a gene. On which chromosome is this gene located? How many transcripts (splice variants) has Ensembl annotated for it? Are these transcribed from the forward or from the reverse strand of the genome assembly?

(b) What is the longest transcript? How long is the protein it encodes? How many exons does it have? Are any of the exons completely or partially untranslated?

(c) Have a look at the General identifiers and the Gene ontology terms for one of the pax6a transcripts (ENSDART0000066224/ENSDART00000066225). Click on some of the links. What is the function of pax6a?

(d) Which PFAM domains does the protein encoded by pax6a contain?

(e) Is there a human ortholog predicted for the zebrafish pax6a gene? What 'type' does it have? Why?

(f) If you have yourself a gene of interest, explore what information Ensembl displays about it!

Advanced questions drawing in other modules:

(1) How does the manual annotation in Vega compare to the Ensembl annotation? Why are there differences?

(2) What does ZFIN say about pax6a?

Answers

(a)

Go to http://www.ensembl.org.

Under 'Search Ensembl' type 'zebrafish pax6a gene'. Click [Go].

On the page with search results click on 'Ensembl protein_coding Gene: ENSDARG00000045045 (ZFIN: pax6a)'.

The zebrafish pax6a gene is located on linkage group 25. Ensembl has two transcripts annotated for this gene. The transcripts are transcribed from the forward strand of the genome assembly.

(b)

Click on the Ensembl Transcript IDs (ENSDART0000066225).

The longest transcript is ENSDART00000066225. The length of this transcript is 2790 base pairs and the length of the encoded protein 451 amino acids.

Click on 'ENSDART0000066225' in case you are not already on the 'Transcript: pax6a' tab.

Click on 'Exons' in the side menu.

ENSDART0000066225 has 13 exons, of which the first one is completely untranslated and the second and last one are partially untranslated.

(C)

Click on 'General identifiers' in the side menu.

Explore some of the links (good places to start are 'ZFIN' and 'UniProtKB/Swiss-Prot').

Do the same for 'Gene ontology'.

Pax6a encodes a nuclear transcription factor involved in pattern formation and brain development.

(d)

Click on 'Domains & features' in the side menu.

The pax6a product contains 2 PFAM domains: Homeobox and Paired_box_N.

(e)

Click on the 'Gene: pax6a' tab.

Click on 'Ortologues' in the side menu.

There is one human ortholog predicted for zebrafish pax6a, PAX6 (ENSG00000007372). It has the type 1-to-many.

Click on the 'Orthologues' next to the 'help' link.

Click on the link for the detailed description, read through 'homology types'.

Click on the human orthologue ENSDARG0000007372, follow the links to its zebrafish orthologues

The type 1-to-many is set because one human gene (PAX6) is the ortholog to two zebrafish genes (pax6a and pax6b)

Exercise 2 – Exploring a region

(a) Go to the region from bp 33300000 to 33500000 on zebrafish chromosome 13. How many contigs make up this portion of the assembly (contigs are contiguous stretches of DNA sequence that have been assembled solely based on direct sequencing information, in the zebrafish assembly there are finished clones, contigs from unfinished clones and whole genome shotgun contigs)?

(b) Do the tilepath clones (i.e. the BAC clones that were sequenced to generate the sequence for the human genome assembly) correspond with the contigs? Note that these clones are not shown by default! Which clone library does the clone containing the fgf8 gene come from?

(c) Zoom in on the fgf8 transcript, including a bit of flanking sequence on both sides. Which marker is located close by? Does this marker appear anywhere else in the genome?

(d) CpG islands are genomic regions that contain a high frequency of CG dinucleotides and are often located near the promoter of mammalian genes. Is there a CpG island associated with the fgf8 transcript? And did the Eponine program (<u>http://www.sanger.ac.uk/Software/analysis/eponine/</u>) predict a transcription start site for the fgf8 transcript?

(e) Export the genomic sequence of the region you are looking at in FASTA format.

(f) If you have yourself a genomic region of interest, explore what information Ensembl displays about it!

Answer

(a)

Go to the Ensembl homepage. Under 'Search Ensembl' type 'zebrafish 13:33300000-33500000'. Click [Go].

This genomic region is made up of 3 contigs, indicated by the alternatingly light and dark blue coloured bars in the 'Contigs' track.

(b)

Click on 'Configure this page' in the side menu. Search for 'Misc regions'. Select 'WGS/Clones assembly'. Click [SAVE and close].

The tilepath clones correspond neatly to the contigs and it is easy to see from which BAC clones which contig sequence in the assembly is derived. The tilepath clones overlap.

Click on 'CR925797' in the 'WGS/Clones assembly' track

In the new menu, clock on the EMBL accession. Read the last lines of the comments.

CR925797 is clone CH211-19418 from the CHORI-211 BAC library.

(C)

Draw a box around the fgf8 transcript. Click on 'Jump to region' in the pop-up menu.

Gene fgf8 overlaps the fgf8 marker

Click on the marker and 'Marker info'

The fgf8 marker is uniquely placed into this position.

(d)

Click on 'Configure this page' in the side menu. Search for 'cpg'. Select 'CpG islands'. Search for 'eponine'. Select 'TSS (Eponine)'. Click [SAVE and close].

There is indeed a CpG island located at the 5' end of the fgf8 transcript. Eponine TSS-finder predicts a transcription start site quite a bit away from the assumed Ensembl fgf8 transcript start site.

(e)

Click on 'Export data' in the side menu. Click on [Next>]. Click on 'HTML'.

Note that the sequence has a header that provides information about the genome assembly (Zv8), the chromosome (13), the start and end coordinates (33420763 and 33536545) and the strand (1):

>13 dna:chromosome chromosome:Zv8:13:33420763:33536545:1

BioMart

Mining data- worked example

Find all protein-coding zebrafish genes on linkage group 1 that have a human orthologue. Display the Ensembl IDs of the zebrafish and human genes plus the chromosomal location of the human gene.

Where and when are these zebrafish genes expressed?

Download the sequence of all available 5' UTRs of these genes.

STEP 1: Either click on 'BioMart' in the top right header bar of the Ensembl home page, or go to <u>http://www.biomart.org/</u> and click on the 'MartView' tab.

EXERCISES and ANSWERS

Note: The answers to these exercises correspond to version 54 of Ensembl. If you use a newer version and your answer doesn't correspond with the given answer, please consult the instructors. Alternatively, you can use version 54 from the Ensembl Archive site.

Exercise 1

Generate a list of all zebrafish genes on chr4 with a ZFIN ID that are expressed in the gastrula shield and have a transmembrane domain. Narrow this down to genes without a human ortholog. Narrow it down again to genes with at least two splice variants.

Download the peptide sequences and make sure the header states the Ensembl ID, a description, the associated gene name and the associated gene DB.

Answer

Go to the Ensembl homepage. Click the BioMart link on the toolbar.

Start with all the zebrafish Ensembl genes:

Choose the 'Ensembl 54' database. Choose the 'Danio rerio genes (Zv8)' dataset.

Now filter for the genes on chromosome 4:

Click on 'Filters' in the left panel. Expand the 'REGION' section by clicking on the + box. Select 'Chromosome - 4'. Make sure the check box in front of the filter is ticked, otherwise the filter won't work. Click the [Count] button on the toolbar.

This should give you 446 / 37435 Genes. Now filter further for genes that are protein coding:

Expand the 'GENE' section by clicking on the + box. Select 'Gene type - protein_coding'. Click the [Count] button on the toolbar.

This should give you 1079 / 24233 Genes. Now for genes with a ZFIN ID

Click 'ID list limit' and choose 'ZFIN ID' Click the [Count] button on the toolbar.

All 1079 have ZFIN IDs

Now select only those genes that are expressed in the shield.

Expand the 'EXPRESSION section by clicking on the + box.

Click 'ZFIN developmental stage data' and browse to 'Gastrula', then select 'Gastrula:Shield'

Click the [Count] button on the toolbar.

You should be down to 136 / 24233 genes now. Select those with a transmembrane domain:

Expand the 'PROTEIN DOMAINS' section by clicking on the + box. Select 'Transmembrane domains' and also 'Only' Click the [Count] button on the toolbar.

This leaves 25 genes. Narrow down further to those without a Human ortholog.

Expand the 'MULTI SPECIES COMPARISONS' section by clicking on the + box.

Select 'Homolog filters' and select 'Orthologous Human Genes -Excluded'

Click the [Count] button on the toolbar.

Down to 3 / 24233. Now only select those genes with alternative splice variants.

Expand the 'GENE' section again by clicking on the + box. Select "Transcript count >=' and enter '2' Click the [Count] button on the toolbar.

One gene left. Now download the cDNA sequence with the Ensembl ID, the associated gene name, gene DB and a description.

Click on 'Attributes' in the left panel. Select the 'Sequences' attributes page.

Select 'Peptide'.

Expand the 'Header Information' section and select 'Ensembl Gene ID', 'Description', 'Associated Gene Name' and 'Associated Gene DB'

Click the [Results] button on the toolbar.

If you are happy with how the results look in the preview, output all the results:

Select 'View All rows as HTML' or export all results to a file.

Note: When you select 'View All rows as HTML', your results will be shown under a new tab in your internet browser.

Although you have filtered for only one gene, your results will contain more than one row. This is because the gene has more than one transcript and the results contain a separate row for each transcript.

Exercise 2

BioMart is a very handy tool when you want to map IDs between different databases. The following is a list of 29 IDs of human proteins from the RefSeq database of NCBI (<u>http://www.ncbi.nlm.nih.gov/projects/RefSeq/</u>):

NP_001218, NP_203125, NP_203124, NP_203126, NP_001007233, NP_150636, NP_150635, NP_001214, NP_150637, NP_150634, NP_150649, NP_001216, NP_116787, NP_001217, NP_127463, NP_001220, NP_004338, NP_004337, NP_116786, NP_036246, NP_116756, NP_116759, NP_001221, NP_203519, NP_001073594, NP_001219, NP_001073593, NP_203520, NP_203522

Generate a list that shows to which Ensembl Gene IDs and to which HGNC symbols these RefSeq IDs correspond. Which of these genes have a zebrafish ortholog?

Answer

Click [New]. Choose the 'Ensembl 53' database. Choose the 'Homo sapiens genes (NCBI36)' dataset.

Click on 'Filters' in the left panel. Expand the 'GENE' section by clicking on the + box. Select 'ID list limit - Refseq protein ID(s)' Enter the list of IDs in the text box (either comma separated or as a list).

Click on 'Attributes' in the left panel. Select the 'Features' attributes page. Expand the 'GENE' section by clicking on the + box. Deselect 'Ensembl Transcript ID'. Expand the 'External' section by clicking on the + box. Select 'HGNC symbol' and 'RefSeq Protein ID'.

Click the [Results] button on the toolbar.

Select 'View All rows as HTML' or export all results to a file. Tick the box 'Unique results only'.

Note: BioMart is 'transcript-centric', which means that it will give a separate row of output for each transcript of a gene, even if you don't include the Ensembl Transcript ID in your output. When you don't want this, use the 'Unique results only' option.

Your results should show 11 genes, most of them Caspase (CASP) genes. Several RefSeq IDs map to the same Ensembl Gene ID and HGNC symbol.

Now narrow down to genes with zebrafish orthologs.

Expand the 'MULTI SPECIES COMPARISONS' section by clicking on the + box.

Select 'Homolog filters' and select 'Orthologous Zebrafsih Genes -Only'

Click the [Count] button on the toolbar.

You will be left with 8 genes.

Exercise 3

List all genes between the markers Z17393 and Z65461. Where did they get their names from?

Answer

Click [New]. Choose the 'Ensembl 54' database. Choose the 'Danio rerio genes (Zv8)' dataset.

Click on 'Filters' in the left panel. Expand the 'REGION' section by clicking on the + box. Enter 'Marker Start: Z17393' and 'Marker End: Z65461'.

Click on 'Attributes' in the left panel. Select the 'Features' attributes page. Expand the 'GENE' section by clicking on the + box. Deselect 'Ensembl Transcript ID'. Select 'Associated Gene Name' and 'Associated Gene DB.

Click the [Results] button on the toolbar.

Select 'View All rows as HTML' or export all results to a file. Tick the box 'Unique results only'.

Your results should show 29 genes. Among these there should be genes with a ZFIN record, genes without a ZFIN record but an entry in Entrez, genes without a ZFIN record but closely related to a human gene (HGNC, check this is really the case by following up vav2 in human and also in ZFIN!) and genes where no good relation could be found, hence the DB column is empty.

Exercise 4

Generate a list of all zebrafish genes on chr 1 that have an human ortholog on human chr 13. Display the gene names, are they the same? Note: This requires you to select an additional data set.

Choose database 'Ensembl 54' and dataset 'Danio rerio genes (Zv8).

Narrow down by filtering for 'REGION' 'Chromosome - 1' and 'MULTI SPECIES COMPARISONS' selecting 'Homolog Filters' 'Orthologuos Human genes -Only'

Click on "Attributes', then 'Features' , deselect 'Ensembl Transcript ID', select 'Associated Gene Name'

Click on 'Dataset' (bottom left) and select '[Ensembl 54] Homo sapiens genes (NCBI36)'

Narrow down by filtering for 'REGION' 'Chromosome - 13' and 'MULTI SPECIES COMPARISONS' selecting 'Homolog Filters' 'Orthologuos Zebrafish genes -Only'

Click on "Attributes', then 'Features' , deselect 'Ensembl Transcript ID', select 'Associated Gene Name'

You will end up with a list where quite a lot of names are identical in zebrafish and human, whereas a few zebrafish genes seem to be in need of renaming.

Exercise 5

Design your own query!
